We are probably living in the most defining period of human history. The period when computing moved from large mainframes to PCs to cloud. But what makes it defining is not what has happened, but what is coming our way in years to come.

What makes this period exciting for some one like me is the democratization of the tools and techniques, which followed the boost in computing. Today, as a data scientist, I can build data crunching machines with complex algorithms for a few dollars per hour. But, reaching here wasn't easy! I had my dark

I DATA HACK (<https://DATAHACK.ANALYTICSVIDHYA.COM>)

techniques, as you don't need to understand them at the start.

So, if you are looking for statistical understanding of these STORIES (<https://WWW.ANALYTICSVIDHYA.COM/BLOG/CATEGORY/STORIES/>) algorithms, you should look elsewhere. But, if you are looking

to equip yourself to start building machine learning project, you WRITE FOR US (<HTTP://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/>) are in for a treat.

CONTACT US (<HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/>)

Broadly, there are 3 types of Machine Learning Algorithms..

1. Supervised Learning

How it works: This algorithm consist of a target / outcome variable (or dependent variable) which is to be predicted from a given set of predictors (independent variables). Using these set of variables, we generate a function that map inputs to desired outputs. The training process continues until the model achieves a desired level of accuracy on the training data.

Techniques you should know!

Let us say, you ask a child in fifth grade to arrange people in his class by increasing order of weight, without asking them their weights! What do you think the child will do? He / she would likely look (visually analyze) at the height and build of people and arrange them using a combination of these visible parameters. This is linear regression in real life! The child has actually figured out that height and build would be correlated to the weight by a relationship, which looks like the equation above.

In this equation:

- Y – Dependent Variable
- a – Slope
- X – Independent variable
- b – Intercept

These coefficients a and b are derived based on minimizing the sum of squared difference of distance between data points and

STORIES (HTTPS://WWW.ANALYTICSVIDHYA.COM/BLOG/CATEGORY/STORIES/)

Linear Regression is of mainly two types: Simple Linear Regression and Multiple Linear Regression. Simple Linear Regression is characterized by one independent variable. And, Multiple Linear Regression (as the name suggests) is characterized by multiple (more than 1) independent variables. While finding best fit line, you can fit a polynomial or curvilinear regression. And these are known as polynomial or curvilinear regression.

Python Code

The logo features the text "Analytics Vidhya" with a blue arrow icon above the "A". Below it says "Learn Everything About Analytics". <http://www.edvancer.in/course>

(<https://datahack.analyticsvidhya.com/co/skilltest-python-for-data-scienc>)

2 Logistic Regression

Don't get confused by its name! It is a classification not a regression algorithm. It is used to estimate discrete values (Binary values like 0/1, yes/no, true/false) based on given set of data points. It uses probability of occurrence of an event by fitting data to a logit function. [CONTACT US \(HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/\)](https://en.wikipedia.org/wiki/Logistic_function) Hence, it is also known as **logit regression**. Since, it predicts the probability, its output values lies between 0 and 1 (as expected).

Again, let us try and understand this through a simple example.

Let's say your friend gives you a puzzle to solve. There are only 2 outcome scenarios – either you solve it or you don't. Now imagine, that you are being given wide range of puzzles / quizzes in an attempt to understand which subjects you are good at. The outcome to this study would be something like this – if you are given a trigonometry based tenth grade problem,

You are 70% likely to solve it. On the other hand, if it is grade 10, probability of getting an answer is only 30%. This is what Logistic Regression provides you.

[HOME \(HTTPS://WWW.ANALYTICSVIDHYA.COM/\)](https://www.analyticsvidhya.com/) [BLOG \(HTTPS://WWW.ANALYTICSVIDHYA.COM/BLOG/\)](https://www.analyticsvidhya.com/blog/) [register now](#)

4. SVM (Support Vector Machine)

It is a classification method. In this algorithm, we plot each data item as a point in n-dimensional space (where n is number of features you have) with the value of each feature being the value of a particular coordinate.

For example, if we only had two features like Height and Hair Length (https://www.analyticsvidhya.com/), first plot these two variables in two dimensional space where each point has two co-ordinates

5. Naive Bayes

It is a classification technique based on Bayes' theorem (https://en.wikipedia.org/wiki/Bayes%27_theorem) with an assumption of independence between predictors. In simple terms, a Naive Bayes classifier assumes that the presence of a particular feature in a class is unrelated to the presence of any

other feature. For example, a fruit may be considered to be an apple if it is about 3 inches in diameter. Even if these features depend on each other or upon the existence of the other, they still contribute to the probability.

These probabilities are called prior probabilities. These build and particularly useful simplicity, Naïve Bayes is a sophisticated classification

[DISCUSS \(HTTPS://DISCUSS.ANALYTICSVIDHYA.COM\)](https://discuss.analyticsvidhya.com)

calculating posterior

($x|c$). Look at the equation

Likelihood Class Prior Probability

[DATAHACK \(HTTPS://DATAHACK.ANALYTICSVIDHYA.COM\)](https://datahack.analyticsvidhya.com)

$$P(c|x) = \frac{P(x|c)P(c)}{P(x)}$$

[STORIES \(HTTPS://WWW.ANALYTICSVIDHYA.COM/BLOG/CATEGORY/STORIES/\)](https://www.analyticsvidhya.com/blog/category/stories/)

Posterior Probability Predictor Prior Probability

[WRITE FOR US \(HTTP://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/\)](https://www.analyticsvidhya.com/about-me/write/)

$$P(c|X) = P(x_1|c) \times P(x_2|c) \times \dots \times P(x_n|c) \times P(c)$$

[CONTACT US \(HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/\)](https://www.analyticsvidhya.com/contact/)

(https://www.analyticsvidhya.com/wp-content/uploads/2015/08/Bayes_rule.png)

Here,

- $P(c|x)$ is the posterior probability of *class (target)* given *predictor (attribute)*.
- $P(c)$ is the prior probability of *class*.
- $P(x|c)$ is the likelihood which is the probability of *predictor given class*.
- $P(x)$ is the prior probability of *predictor*.

Example: Let's understand it using an example. Below I have a

training data set of weather and corresponding target variable (https://www.analyticsvidhya.com/blogs/160101-weather-based-prediction-for-sport-matches) to predict whether players will play or not based on weather condition. Let's follow the below steps to

Step 3: Now, use Naive Bayesian equation to calculate the

WRITE FOR US (HTTP://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/)

posterior probability is the outcome of prediction.

CONTACT US (HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/)

Problem: Players will play if weather is sunny, is this statement is correct?

We can solve it using above discussed method, so $P(\text{Yes} | \text{Sunny}) = P(\text{Sunny} | \text{Yes}) * P(\text{Yes}) / P(\text{Sunny})$

Here we have $P(\text{Sunny} | \text{Yes}) = 3/9 = 0.33$, $P(\text{Sunny}) = 5/14 = 0.36$, $P(\text{Yes}) = 9/14 = 0.64$

Now, $P(\text{Yes} | \text{Sunny}) = 0.33 * 0.64 / 0.36 = 0.60$, which has higher probability.

Naive Bayes uses a similar method to predict the probability of

different class based on various attributes. This algorithm is
 cation and with problems having
 multiple classes.

KNN can easily be mapped to our real lives. If you want to learn about a person, of whom you have no information, you might like to find out about his close friends and the circles he moves in and gain access to his/her information!

Things to consider before selecting KNN:

- KNN is computationally expensive
- Works on pre-processing stage more before going for KNN

How K-means forms cluster:

1. K-means picks k number of points for each cluster known as centroids.
2. Each data point forms a cluster with the closest centroids i.e. k clusters.
3. Finds the centroid of each cluster based on existing cluster members. Here we have new centroids.
4. As we have new centroids, repeat step 2 and 3. Find the closest distance for each data point from new centroids and get associated with new k -clusters. Repeat this process until convergence occurs i.e. centroids does not change.

How to determine value of K:

 [\(https://www.analyticsvidhya.com/\)](https://www.analyticsvidhya.com/)

We have clusters and each cluster has its own centroid. Sum of square of difference between centroid and the

8. Random Forest

[WRITE FOR US \(\[HTTP://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/\]\(http://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/\)\)](http://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/)
Random Forest is a trademark term for an ensemble of decision trees. In Random Forest, we've collection of decision trees (so known as Forest). To classify a new object based on attributes, each tree gives a classification and we say the tree "votes" for that class. The forest chooses the classification having the most votes (over all the trees in the forest).

Each tree is planted & grown as follows:

1. If the number of cases in the training set is N, then sample of N cases is taken at random but *with replacement*. This sample will be the training set for growing the tree.
2. If there are M input variables, a number m<<M is specified such that at each node, m variables are selected at random out of the M and the best split on these m is used to split the

node. The value of m is held constant during the forest (https://www.analyticsvidhya.com/blog/2015/08/...).
e largest extent possible. There is no pruning.

9. Dimensionality Reduction Algorithms

In the last 4-5 years, there has been an exponential increase in data capturing at every possible stages. Corporates/ Government Agencies/ Research organisations are not only coming with new sources but also they are capturing data in great detail.

For example: E-commerce companies are capturing more details about customer like their demographics, web crawling history, what they like or dislike, purchase history, feedback and

many others to give them personalized attention more than ever. (<https://www.analyticsvidhya.com/>)

As a data scientist, the data we are offered also consist of many [HOME](https://WWW.ANALYTICSVIDHYA.COM/) [BLOG](https://WWW.ANALYTICSVIDHYA.COM/BLOG/) [JOBS](https://WWW.ANALYTICSVIDHYA.COM/JOBS/) [TRAININGS](https://WWW.ANALYTICSVIDHYA.COM/TRAININGS/) [DISCUSS](https://DISCUSS.ANALYTICSVIDHYA.COM/)

([The reason of taking the log](https://www.analyticsvidhya.com/categories))

underlying assumption in logistic regression is

[WRITE FOR US \(HTTP://WWW.ANALYTICSVIDHYA.COM/ABOUT-ME/WRITE/\)](https://www.analyticsvidhya.com/about-me/write)

that the probability is governed by a step

function whose argument is linear in the

[CONTACT US \(HTTPS://WWW.ANALYTICSVIDHYA.COM/CONTACT/\)](https://www.analyticsvidhya.com/contact)

attributes. First of all the assumption of linearity

otherwise introduces bias. However, logistic

regression being a parametric model some bias

is inevitable. The reason to choose a linear

relationship is not because its easy to solve but

because a higher order polynomial introduces

higher bias and one would not like to do so

without good reason.

Now coming to the choice of log, it is just a convention. Basically, once we have decided to go with a linear model, in the case of one attribute we model the probability by

$$p(x) = f(ax+b)$$

such that $p(-\infty)=0$ and $p(\infty)=0$. It so

that this is satisfied by

[p\(x\) = exp\(ax+b\)/\(1 + exp\(ax+b\)\)](https://www.analyticsvidhya.com)

93085)

Nice summary!

@Huzefa: you shouldn't replace the "~" in the R code, it basically means "as a function of". You can also keep the ":" right after, it stands for "all other variables in the dataset provided". If you want to be explicit, you can write $y \sim x_1 + x_2 + \dots$ where $x_1, x_2 \dots$ are the names of the columns of your data.frame or data.table.

Further note on formula specification: by default R adds an intercept, so that $y \sim x$ is equivalent to $y \sim 1 + x$, you can

Somewhat irresponsible article since it does not mention

any measure of performance and only gives cooking it. Standing what algorithm does what it. Cooking recipes like these are the ones that place people in Drew Conway's danger zone.
